

you're an extrovert or an introvert — instead, it tells you your propensity toward extraversion. Every trait is graded on a spectrum, with a few people far out on the extremes and a lot of people in the middle.

The other thing that makes the Big Five different is it lets you easily compare your score to others'. We're going to show you how your personality compares with that of the average American. And once you get your results, you can invite friends and relatives to compare your personality to theirs. (In the meantime, you'll be stuck comparing yourself to the average FiveThirtyEight staffer.)

So what are you waiting for? Find out who you really are — take the quiz for yourself!

YOUR BIG FIVE SCORES

National

Openness to experience

58 out of 100

Agreeableness

58 out of 100

Conscientiousness

50 out of 100

Negative emotionality

50 out of 100

Extraversion

29 out of 100

But wait — there's more! Each of the Big Five traits has something different to tell you about your life, and all five break down into subtraits. For example, someone can be highly extraverted because they're really social or because they're super assertive. We're going to show you those subtraits too. Although scientists generally agree on the Big Five traits, the specific subtraits are still being debated. We're using [the ones that have been identified by Christopher Soto](#), a professor of psychology at Colby College in Maine. Soto and his colleague Oliver John developed a major Big Five test, the BFI-2. (You can read more about it on [the website for Soto's lab](#).) We've used questions from that quiz with their permission and consulted with Soto in the development of our quiz. Read on to see what each trait reveals about who you really are.

Moderate openness to experience: Openness is all about intellectual engagement and exploration. People on the high end are curious, experimental and probably artsy-fartsy. People on the low end lean toward rigidity — think the glowering dad or crusty old dean in every '80s teen movie. Those who score highly on this trait are at an increased risk of substance use. A low score can correlate with not really seeing what's so bad about fascism. All things considered, you're in a pretty good place right here in between.

AGREEABLENESS

58 out of 100

Moderate agreeableness: You have to be pretty dang un-agreeable to truly count as a low agreeableness person. A lot of the outcomes that correlate with low agreeableness, like being chronically bullied (or bullying) or having a criminal record, don't kick in until someone's score is down in the 10th percentile. So even though all the Big Five traits operate on a spectrum — with the people in the middle tending to experience a little of what both poles feel to the extreme — the population of people who count as “moderately agreeable” is particularly large. (It's just that some of you may have a little less tendency toward empathy, compassion and trust of your fellow human beings than others.) You're no goody-goody, but you're also not what the professionals might refer to as “a selfish jerk.”

CONSCIENTIOUSNESS

50 out of 100

Moderate conscientiousness: The highly conscientious are detail-oriented goal-setters who dot their i's, cross their t's and keep detailed spreadsheets of all the times they did that. They tend to do well at work, be productive at home and lean toward being religious. People

FiveThirtyEight

and tend to not finish the chores they said they'd get done. There are benefits and drawbacks to people on both ends of the spectrum, but if we had to choose a roommate, we'd pick you — someone in the middle.

Your conscientiousness subtraits

How you compare

Moderate negative emotionality: You don't exactly have a propensity toward sadness, anger and anxiety. But you also aren't exactly lacking those tendencies, either. All the Big Five traits operate on a spectrum — the people in the middle tend to experience a little of what both poles feel to the extreme. And that means you're also likely getting a taste of the outcomes correlated with both those poles, too. People who score high on negative emotionality have rocky relationships — maybe you've had one relationship that brought that side out more than others. The low negative emotionality folks will cheerfully work the same job for decades with no burnout — maybe you take a little longer to reach burnout stage (even if you eventually do). If you're reading this and thinking, "Hey, doesn't that just make me a normal human?" Well, statistically, yes, that would be how bell curves work, wouldn't it? Don't worry. There's probably another personality trait where you're more extreme.

Your negative emotionality subtraits

EXTRAVERSION

29 out of 100

Low extraversion: We live in a society that generally values and rewards extraversion, and that can make life tough for a more withdrawn person. Science tends to emphasize the downer aspects of your personality — you probably have difficulty making friends and finding people to date, for instance. You might also have a low opinion of your own looks. But being an introvert isn't all bad. Some scientists think low extraversion has protected humans from disease — [you can't pick up a bug from people if you avoid people](#). And [one study even found](#) a lower prevalence of extraversion in places where contagious diseases were historically common. One of the best bits of advice for the less extraverted is to find spaces where they get to live the way they want and where their personalities are valued. That's probably why being less extraverted is correlated with choosing, and excelling at, jobs that require working alone. And there is a higher prevalence of introverts [in the American West](#). Have you considered a career in ranching?
